	APPENDIX 1. PREFERRED THINNING SCHEDULE	9

1 Trial Layout and Treatment Categories

The split-plot design consists of 102 whole-plots or “installations” (5 ecological site classes x 6 planting densities, replicated 3-5 times). Each 1-hectare installation is split into 4 weeding and thinning sub-plots or “treatment plots” (see Table 1).

Table 1. Plot Vegetation Management Treatments

Plot	Treatment	Treatment Description
C	Control	Do not apply vegetation management treatments or otherwise disturb vegetation
W	Weeding	Apply herbicide to (or manually weed) herbaceous and deciduous vegetation exceeding competition thresholds
WT	Weeding and Thinning	Apply both weeding (“W”) and thinning (“T”) treatments
T	Thinning	Remove remaining deciduous trees and shrubs, and thin coniferous trees to target density

The installations are organized in 17 groups of 6, each installation within a group having a different target crop tree density. The target densities are shown in Table 2 as stems per ha, per treatment plot (0.25ha), and per measurement plot (0.1ha). Weeding treatments are complete. The thinning treatment, applicable to the WT and T treatment plots, will involve identifying and retaining the appropriate number of target trees and removing all other coniferous and deciduous trees (including willow and alder shrubs). In planted installations the target after-thinning density (stems per ha) is the same as the original target planting density. In non-planted installations, natural coniferous regeneration in the WT and T plots will be thinned if its density exceeds 4,444 stems per ha (i.e. the maximum planting density). One installation (4-2-0), scheduled as non-planted but erroneously planted, will not be retained in the experiment and has been excluded from the thinning schedule.

Table 2. Target Densities and Equivalent Inter-tree Distances

Code	Target Density (stems/ha)	Target Plot Densities (stems per treatment and measurement plot)	Desired Inter-tree Distance (m)
0 or 9	0	1111/444 ¹	1.5 ²
816	816	204/82	3.5
1111	1111	278/111	3.0
1600	1600	400/160	2.5
2500	2500	625/250	2.0
4444	4444	1111/444	1.5

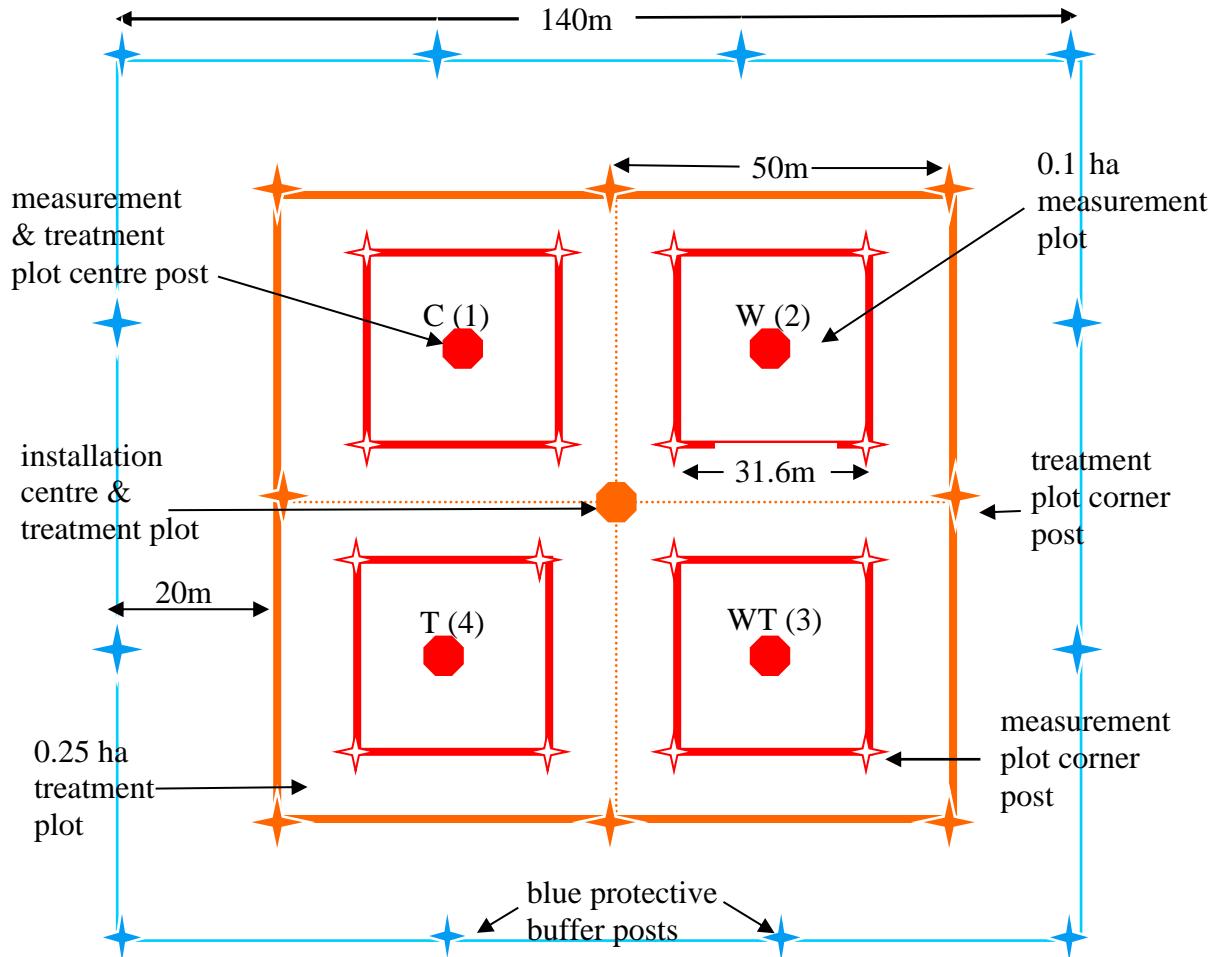

Figure 1 shows the layout of a standard installation. In some installations treatment plots have been realigned or separated to fit into the targeted site. In one installation the designated treatments have had to

¹ Or less depending on the actual density of natural regeneration.

² Or more depending on the actual density of natural regeneration.

be switched between treatment plots because of accidental thinning. Careful attention must therefore be paid to plot maps and the thinning schedule to ensure that the correct plots are thinned.

Figure 1. Installation Diagram

2 Thinning Schedule

A *preferred thinning window* (preferred earliest and latest year for thinning) was established for each installation using the following criteria:

- Earliest – the first year that the average height of pine in either the T or WT treatment plot is projected to exceed 3.0m by the end of the growing season;
- Latest – the earliest of either 2014 or the first year that the average height of pine in either the T or WT treatment plot is projected to exceed 5.0m by the end of the growing season.

All T and WT plots within each group of installations should be thinned during the same year, even though this may mean that some of the plots are not within the preferred thinning window. A *preferred group thinning year* has been identified for each group as follows:

- 2011: Group 4-1 (contains an installation disturbed accidentally in 2010);
- 2012: Remaining groups where all planted installations are forecast to be within the preferred thinning window;
- 2013: Remaining groups where the majority of installations (4 or more out of 6) are within the preferred thinning window;
- 2014: Remaining groups.

The resulting Preferred Thinning Schedule is shown in Appendix 1. The schedule is also available in Microsoft Excel format, together with details of the scheduling information and calculations.

Information contained in the *schedule* was calculated as follows.

- *Average Pine Height.* Projected to the end of the growing season of the preferred group thinning year from the latest full measurement (conducted in 2010 or 2011), based on the periodic annual increment observed since the previous measurement.
- *Retained Stems per Ha.* For planted plots this always equates to the Target Planting Density. (Mortality, although considerable on some plots, has so far always been more than offset by ingress of natural regeneration.) For non-planted plots the retained stems per ha will be the lesser of 4,444 or the actual ingress stems per ha.
- *Retained Stems per Treatment Plot and per Measurement Plot* (0.25ha and 0.1ha respectively). Calculated from the retained stems per ha.
- *Removed Conifer Stems per Treatment Plot and Measurement Plot.* Calculated from the total live coniferous stems per ha estimated as of 2011, based on the last full measurement (2010 or 2011) and planting stock survival to 2011, less the retained stems per ha as calculated above.
- *Removed Deciduous Stems per Treatment Plot and Measurement Plot.* Number of deciduous stems (30cm+ in height) as measured and estimated at the last full measurement (2010 or 2011). The estimate does not include willow and alder.

Note that no adjustments are made for changes in densities that may occur as a result of ingress or mortality between the last measurement and the thinning. The schedule will be updated each year as new data becomes available. If possible, thinning should be conducted for each group of installations in the indicated preferred group thinning year. The numbers of groups currently scheduled per year are:

• 2011	1
• 2012	8
• 2013	6
• 2014	2

Thinning will be undertaken after July 15 of the year scheduled, and after the plot has been measured (full or check). It must be done while the plot is snow-free, and completed for the whole group before May 31 of the following calendar year. If adherence to the preferred schedule is not possible, thinning of the group should be conducted the year following the preferred group thinning year, and completed for all installations in the trial by May 31, 2015. The identities of tagged and numbered trees that are

removed during the thinning operation are to be recorded during the first routine plot measurement following thinning.

3 Thinning Method

The trial involves an experimental range of thinning intensities and target post-thinning densities. In all other respects the thinning method will follow or approximate the best operating practices of FGYA members. Thinning will be conducted on all T and WT treatment plots where deciduous competition exists and / or where the actual number of live coniferous stems per plot exceeds the target identified in the schedule.

3.1 Tree Selection

All deciduous trees (including willow and alder shrubs) 30cm+ in height are to be removed.

Coniferous trees to be removed and “keep” trees to be retained after thinning will be identified based on two sometimes conflicting sets of criteria: spacing between trees and tree characteristics. Ideally, retained trees will be distributed at inter-tree distances approximating the squarely-spaced planting densities shown in Table 2. In practice, the distance between a retained tree and its nearest neighbor will be permitted to exceed the inter-tree distances shown in Table 2 depending on tree health and condition (see below). Post-thinning inter-tree distances less than 50% of the values in Table 2 will normally be avoided, except where no other alternatives exist to maintain target densities (e.g. in plots with a very high incidence of trees with priority 1 or 2 for removal). Conifer trees less than 15cm in height are not required to be removed.

Priority rules for coniferous tree removal are listed below. Note that the rules make a distinction between *target plot density* (the scheduled numbers of retained trees per treatment and measurement plot) and *desired inter-tree distance* (the distance between any retained tree and its nearest neighbor). Target plot densities and equivalent desired inter-tree distances are shown in Table 2.

1. Trees always to be removed, regardless of target plot density and desired inter-tree distances:
 - Dead;
 - Infected by *Armillaria* root disease;
 - Attacked by Warren root collar weevil and unlikely to survive (vigour = AU).
 - With western gall rust encircling more than 50% of the main stem and unlikely to survive (vigour = AU).
2. Trees which are to be removed in preference to maintenance of desired inter-tree distances, but to be left if removal would result in failure to meet the target plot density:
 - Injured or deformed: dead top, mechanical or browsing damage, severe J-root, crook or lean;
 - Diseased: needle casts, blister and gall rusts, *Atropellis* canker;
 - Within 2m of trees that have died from *Armillaria* root disease.Trees that are mildly or moderately injured, deformed or diseased may be retained where necessary to fill gaps that are otherwise likely to result in permanent loss of tree cover, providing that the retained trees are considered likely to survive until rotation and unlikely to threaten the health of other trees.

3. Trees which are to be removed providing that the distance between retained trees does not exceed the planned inter-tree distance (Table 2) by more than 50%, and that the target plot density is met:
 - Sub-dominant or suppressed crowns;
 - Poor stem form (e.g. lack of straightness, replaced leader, forked) relative to alternative trees;
 - Poor height, diameter and / or terminal growth relative to alternative trees;
 - Balsam or alpine fir.
4. Other trees to be removed as required to reduce density to target levels:
 - Select so as to equalize distances between retained trees.

It follows that retained trees must be alive, free from Armillaria root disease, and not dying as a result of attack by *Hylobius* or western gall rust. To the extent permitted by pre-thinning densities and tree removal rules, retained trees should also be:

- Pine or spruce ;
- With healthy dominant or co-dominant crowns;
- Without serious injury or disease;
- Straight stemmed;
- Vigorous in growth;
- Evenly spaced.

“Keep” trees in the planted 0.1ha measurement plots will be flagged with ribbon ahead of the thinning operation, preferably during the preceding scheduled full or check measurement, according to the following procedure.

1. Locate where possible every tree that was originally planted and tagged. (Copies of the tree information table from the trial database will be made available for this purpose.)
2. At each original individual tree planting location determine, based on the removal priority rules described above, whether the tree is to be kept, and / or if there is an adjacent conifer with lower priority for removal that should be retained instead.
3. Flag the trees provisionally identified for retention according to step 2.
4. Count the total number of trees flagged in the measurement plot, and again using the removal priority rules described above, add or remove flags to achieve the targeted retention density. (The number of retained coniferous stems must be within 5% of the scheduled value for the measurement plot.)
5. Ensure that ribbon is conspicuously placed on lateral branches and orientated with regard to the direction of swathes to be followed during the thinning operation. There is no requirement to permanently tag previously unmarked trees at this stage of the trial, and ribbon must not be tied in such a way that it will restrict growth or damage the tree.

The flagging procedure is not applicable for non-planted plots or the portions of planted treatment plots outside the measurement plots. In these situations thinning may be carried out by trained and orientated operators without prior flagging of keep trees, using the following procedure.

1. Become orientated to the required levels of retention and removal by first completing thinning of the pre-flagged planted measurement plot. (In the case of non-planted plots orientation may be based on planted measurement plots thinned to the maximum target density of 4,444 stems per ha.)
2. Proceed to thin a small area (not more than 100m²) based on the orientation, removal priority rules, and target inter-tree distances.
3. Establish a “back plot” in the area thinned, count the number of retained trees in the back plot and check that removal priority rules have been adhered to.
4. Proceed to thin the remainder of the plot, adjusting the thinning intensity according to the results of the back plot.
5. Continue to establish back plots after thinning small areas until results confirm that the thinning targets and priorities are being achieved. (The average number of retained coniferous stems must be within 5% of the scheduled value for the measurement plot, and within 10% of the scheduled value for the whole treatment plot.)
6. Place a minimum of 4 back plots (one on each of the 4 sides) in the portions of the treatment plot lying outside the measurement plot, and a minimum of 4 back plots in each non-planted measurement plot.

It is suggested that back plots be square and the sizes (dependent on target densities) be as shown in Table 3. The sizes are selected to fit within the areas between the perimeters of the measurement and treatment plots, and to accommodate 5 to 11 target stems.

Table 3. Back-Plot Sizes and Target Tree Counts

Target Stems per Ha	Plot Size (m)	Target Stems per Plot
816	8 x 8	5
1111	8 x 8	7
1600	8 x 8	10
2500	5 x 5	6
4444	5 x 5	11

3.2 Work Quality

The following criteria will be used to judge the quality of the thinning work.

1. Deciduous removal:

- No aspen, poplar, birch, willow or alder 30cm+ should remain on the plot.
2. Retained conifer stems per plot and inter-tree distances:
- The number of retained coniferous stems must be within 5% of the scheduled value for the measurement plot, and within 10% of the scheduled value for the whole treatment plot.
 - Inter-tree distance should not be less than 50% of the desired value, and should not exceed the desired value by more than 50% EXCEPT where this is necessitated by removal priority rule #1 or 2 (see Section 3.1).
3. Retained tree characteristics:
- No retained trees should be dead, or be dying from attack by Armillaria, Hylobius or western gall rust.
 - Retained trees should show as many of the following characteristics as are possible given the removal priority rules:
 - Pine or spruce species;
 - Healthy dominant or co-dominant crowns;
 - No serious injury or disease;
 - Straight stems;
 - Good terminal growth.
4. Thinning damage:
- Retained trees must not have thinning-related damage.
 - No ribbon should remain on main stems and ribbon on lateral branches should be either removed or loose enough not to restrict growth.
 - Every effort must be made to avoid cutting trees designated for retention in the plot being thinned or any tree in the adjacent C or W plot. If the thinner unintentionally cuts a designated leave tree in a T or WT plot, he should replace it with the closest tree that best meets the priority rules for retention.
5. Thinning debris:
- No cut trees or brush are to be left leaning against or lying on retained trees.
 - The leader of any retained tree must be free of debris.
 - All downed slash must be less than 1m above the ground.
 - No cut trees or brush are to be left in the C or W treatment plot.
6. Stumps:
- Stumps of thinned trees are to be less than 15cm tall.
 - Stems must be completely cut through, with no hinges.
